Modern ML: New Learning Approaches

Modern applications: massive amounts of raw data.

Techniques that best utilize data, minimizing need for expert/human intervention. 成仍为升級

Paradigms where there has been great progress.

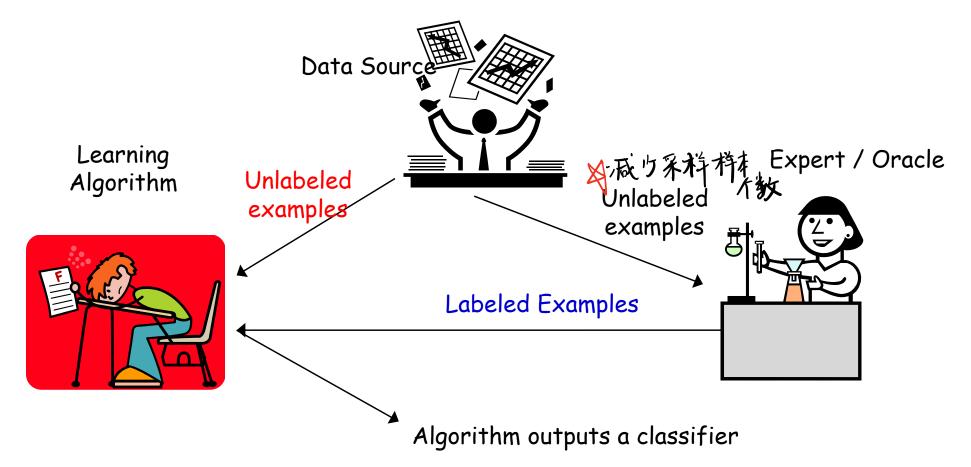

Semi-supervised Learning, (Inter)active Learning.

Semi-Supervised Learning

$$S_l = \{(x_1, y_1), ..., (x_{m_l}, y_{m_l})\}$$

 x_i drawn i.i.d from D, $y_i = c^*(x_i)$

 $S_u = \{x_1, ..., x_{m_u}\}$ drawn i.i.d from D

Goal: h has small error over D.

$$\operatorname{err}_{D}(h) = \Pr_{x \sim D}(h(x) \neq c^{*}(x))$$

以 成 少 5 注 化 消 光 .

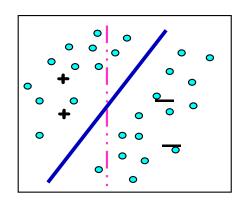

Semi-supervised Learning

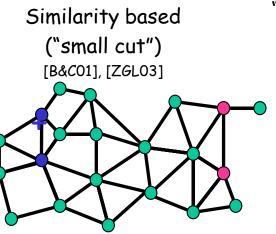

Key Insight/Underlying Fundamental Principle

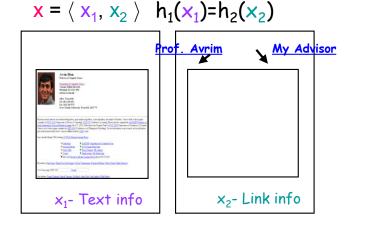

Unlabeled data useful if we have a bias/belief not only about the form of the target, but also about its relationship with the underlying data distribution.

E.g., "large margin separator" [Joachims '99]

"self-consistent rules" [Blum & Mitchell '98]

 Unlabeled data can help reduce search space or re-order the fns in the search space according to our belief, biasing the search towards fns satisfying the belief (which becomes concrete once we see unlabeled data).

A General Discriminative Model for SSL

[BalcanBlum, COLT 2005; JACM 2010]

As in PAC/SLT, discuss algorithmic and sample complexity issues.

Analyze fundamental sample complexity aspects:

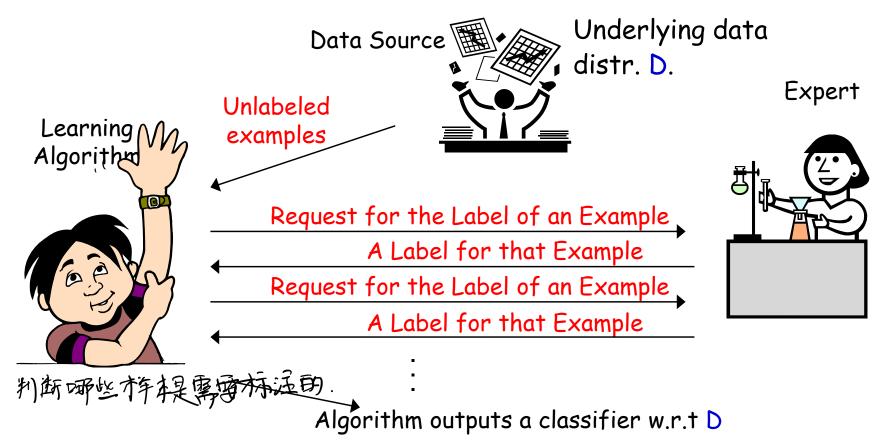

- · How much unlabeled data is needed.
 假设空间、批译模型(线性、指数))、时确定的
 - · depends both on complexity of H and of compatibility notion.
- Ability of unlabeled data to reduce #of labeled examples.
 - compatibility of the target, helpfulness of the distrib.
- Survey on "Semi-Supervised Learning" (Jerry Zhu, 2010)
 explains the SSL techniques from this point of view.
- Note: the mixture method that Tom talked about on Feb 25th can be explained from this point of view too. See the Zhu survey.

Active Learning

Additional resources:

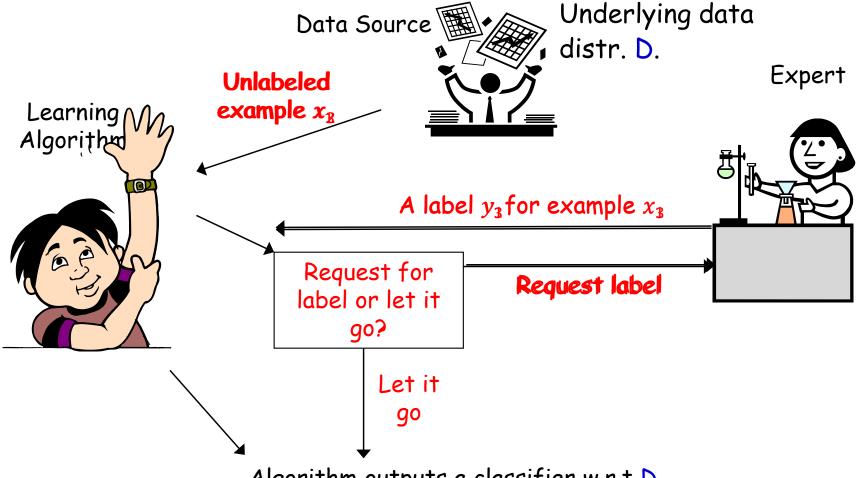

- Two faces of active learning. Sanjoy Dasgupta. 2011.
- Active Learning. Bur Settles. 2012.
- Active Learning. Balcan-Urner. Encyclopedia of Algorithms. 2015

Batch Active Learning

- · Learner can choose specific examples to be labeled.
- Goal: use fewer labeled examples [pick informative examples to be labeled].

Selective Sampling Active Learning

- Algorithm outputs a classifier w.r.t D
- Selective sampling AL (Online AL): stream of unlabeled examples, when each arrives make a decision to ask for label or not.
 - Goal: use fewer labeled examples [pick informative examples to be labeled].

What Makes a Good Active Learning Algorithm?

- Guaranteed to output a relatively good classifier for most learning problems.
- Doesn't make too many label requests.
 Hopefully a lot less than passive learning and SSL.
- Need to choose the label requests carefully, to get informative labels.

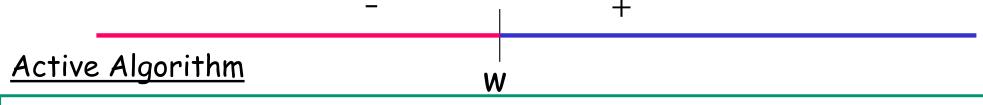

Can adaptive querying really do better than passive/random sampling?

- YES! (sometimes)
- We often need far fewer labels for active learning than for passive.
- This is predicted by theory and has been observed in practice.

Can adaptive querying help? [CAL92, Dasgupta04]

倒值函数 假设空间

• Threshold fns on the real line: $h_w(x) = 1(x \ge w)$, $C = \{h_w : w \in R\}$

- Get N unlabeled examples
- How can we recover the correct labels with $\ll N$ queries?
- · Do binary search! Just need O(log N) labels! 菜一个样,是正:找在题:找在 +
- · Output a classifier consistent with the N inferred labels
- Output a classifier consistent with the N inferred labels.
- 道半监督所転档本数 \cdot N = $O(1/\epsilon)$ we are guaranteed to get a classifier of error $\leq \epsilon$.

Passive supervised: $\Omega(1/\epsilon)$ labels to find an ϵ -accurate threshold.

Active: only $O(\log(1/\epsilon))$ labels. Exponential improvement. つう动きョン 所界 标注的の名成分

Uncertainty sampling in SVMs common and quite useful

in practice. E.g., [Tong & Koller, ICML 2000; Jain, Vijayanarasimhan & Grauman, NIPS 2010; Schohon Cohn, ICML 2000] 然后要找不确定性大的点。即:高分类器更近的气

Active SVM Algorithm

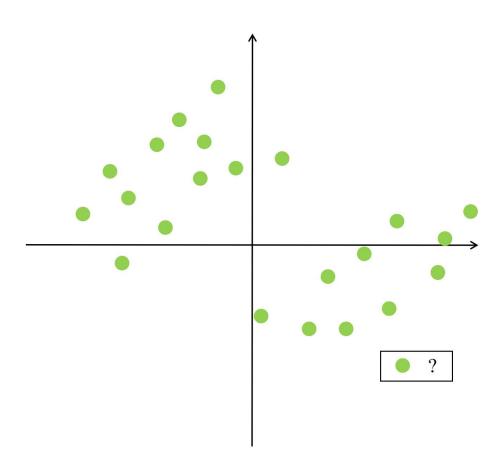

- At any time during the alg., we have a "current guess" \mathbf{w}_{t} of the separator: the max-margin separator of all labeled points so far.
- Request the label of the example closest to the current separator.

Active SVM seems to be quite useful in practice.

[Tong & Koller, ICML 2000; Jain, Vijayanarasimhan & Grauman, NIPS 2010]

Algorithm (batch version)

Input $S_u = \{x_1, ..., x_{m_u}\}$ drawn i.i.d from the underlying source D

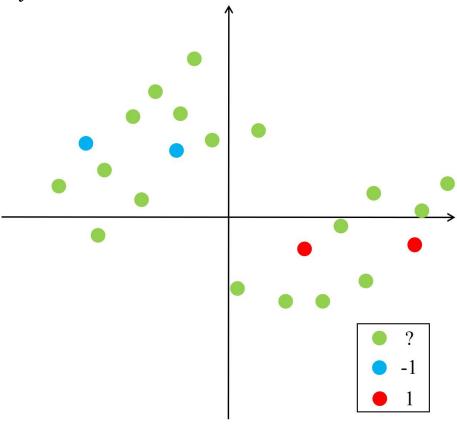

Active SVM seems to be quite useful in practice.

[Tong & Koller, ICML 2000; Jain, Vijayanarasimhan & Grauman, NIPS 2010]

Algorithm (batch version)

Input $S_u = \{x_1, ..., x_{m_u}\}$ drawn i.i.d from the underlying source D

Start: query for the labels of a few random x_i s.

Active SVM seems to be quite useful in practice.

[Tong & Koller, ICML 2000; Jain, Vijayanarasimhan & Grauman, NIPS 2010]

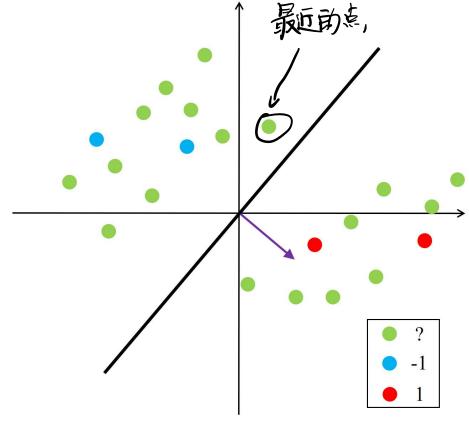

Algorithm (batch version)

Input $S_u = \{x_1, ..., x_{m_u}\}$ drawn i.i.d from the underlying source D

Start: query for the labels of a few random x_i s.

For
$$t = 1,,$$

• Find w_t the max-margin separator of all labeled points so far.

Active SVM seems to be quite useful in practice.

[Tong & Koller, ICML 2000; Jain, Vijayanarasimhan & Grauman, NIPS 2010]

Algorithm (batch version)

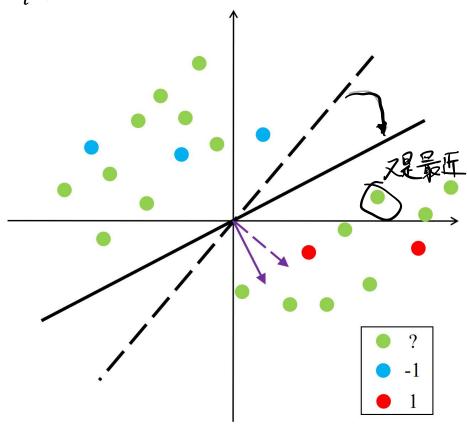

Input $S_u = \{x_1, ..., x_{m_u}\}$ drawn i.i.d from the underlying source D

Start: query for the labels of a few random x_i s.

For t = 1,,

- Find w_t the max-margin separator of all labeled points so far.
- Request the label of the example closest to the current separator: minimizing $|x_i \cdot w_t|$.

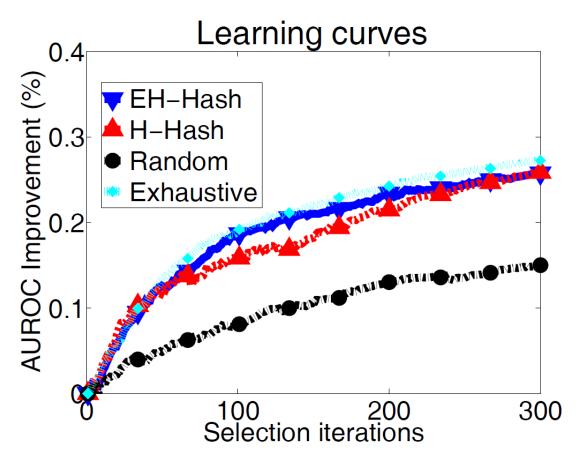

(highest uncertainty)

Active SVM seems to be quite useful in practice.

E.g., Jain, Vijayanarasimhan & Grauman, NIPS 2010

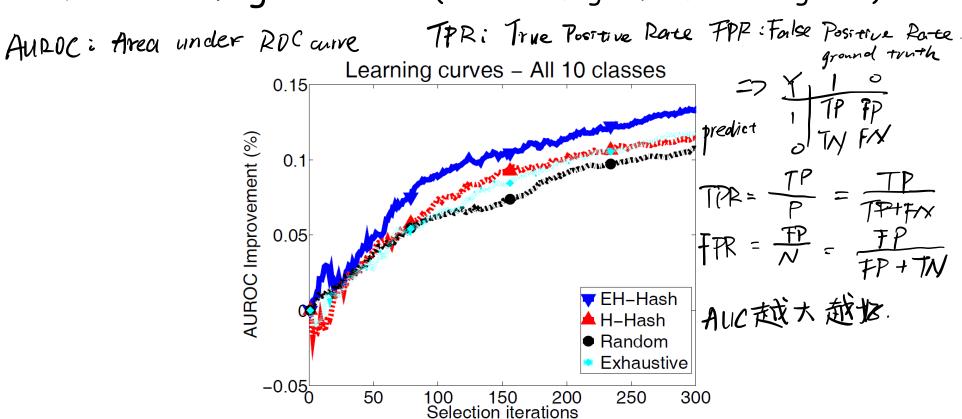

Newsgroups dataset (20.000 documents from 20 categories)

Active SVM seems to be quite useful in practice.

E.g., Jain, Vijayanarasimhan & Grauman, NIPS 2010

CIFAR-10 image dataset (60.000 images from 10 categories)

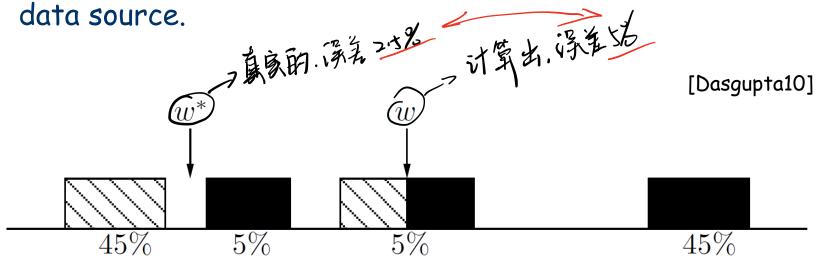

Active SVM/Uncertainty Sampling

- Works sometimes....
- However, we need to be very very very careful!!!

 森村广,采样谓出的分布与原作分种的海差

 Myopic, greedy technique can suffer from sampling bias.

 - A bias created because of the querying strategy; as time goes on the sample is less and less representative of the true data source.

Active SVM/Uncertainty Sampling

- Works sometimes....
- However, we need to be very very careful!!!

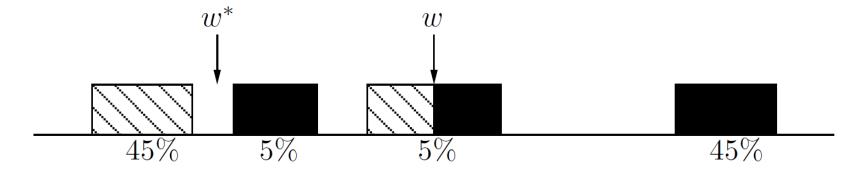

Active SVM/Uncertainty Sampling

- Works sometimes....
- However, we need to be very very careful!!!
 - Myopic, greedy technique can suffer from sampling bias.
 - Bias created because of the querying strategy; as time goes on the sample is less and less representative of the true source.
 - Observed in practice too!!!!

 Main tension: want to choose informative points, but also want to guarantee that the classifier we output does well on true random examples from the underlying distribution.

Safe Active Learning Schemes

Disagreement Based Active Learning Hypothesis Space Search

[CAL92] [BBL06]

[Hanneke'07, DHM'07, Wang'09, Fridman'09, Kolt10, BHW'08, BHLZ'10, H'10, Ailon'12, ...]

Version Spaces 真实潜血线器

- X feature/instance space; distr. D over $X: \overline{c}^*$ target fnc
- Fix hypothesis space H.

```
Definition (Mitchell'82) Assume realizable case: c^* \in H.
 Given a set of labeled examples (x_1, y_1), ..., (x_{m_l}, y_{m_l}), y_i = c^*(x_i)
 Version space of H: part of H consistent with labels so far.
 I.e., h \in VS(H) iff h(x_i) = c^*(x_i) \ \forall i \in \{1, ..., m_l\}.
```

Version Spaces

- X feature/instance space; distr. D over X; c^* target fnc
- Fix hypothesis space H.

Definition (Mitchell'82) Assume realizable case: $c^* \in H$.

Given a set of labeled examples (x_1, y_1) , ..., (x_{m_1}, y_{m_1}) , $y_i = c^*(x_i)$

Version space of H: part of H consistent with labels so far.

E.g.,: data lies on circle in R², H = homogeneous linear seps.

+ region of disagreement in data space

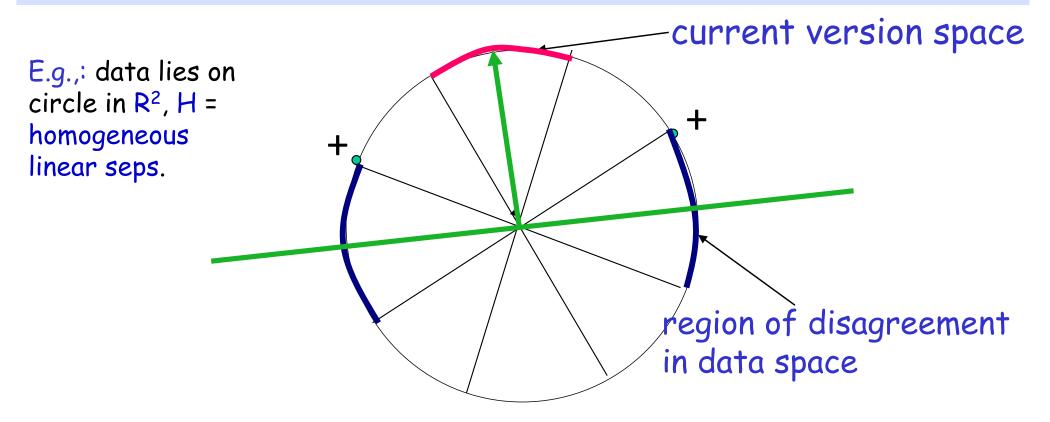

Version Spaces. Region of Disagreement

Definition (CAL'92)

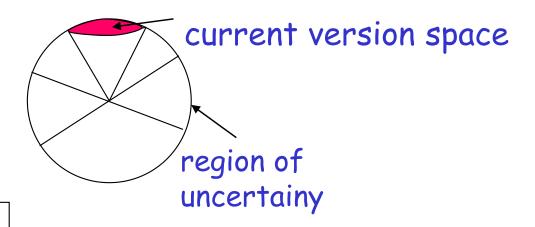

Version space: part of H consistent with labels so far.

Region of disagreement = part of data space about which there is still some uncertainty (i.e. disagreement within version space)

 $x \in X, x \in DIS(VS(H))$ iff $\exists h_1, h_2 \in VS(H), h_1(x) \neq h_2(x)$

Disagreement Based Active Learning [CAL92]

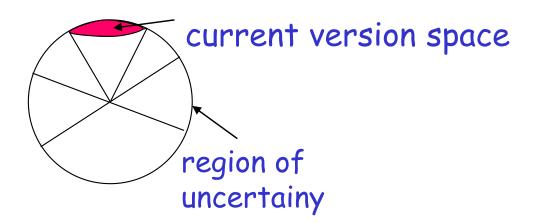

Algorithm:

Pick a few points at random from the current region of uncertainty and query their labels.

Stop when region of uncertainty is small.

Note: it is active since we do not waste labels by querying in regions of space we are certain about the labels.

Disagreement Based Active Learning [CAL92]

Algorithm:

Query for the labels of a few random x_i s.

Let H_1 be the current version space.

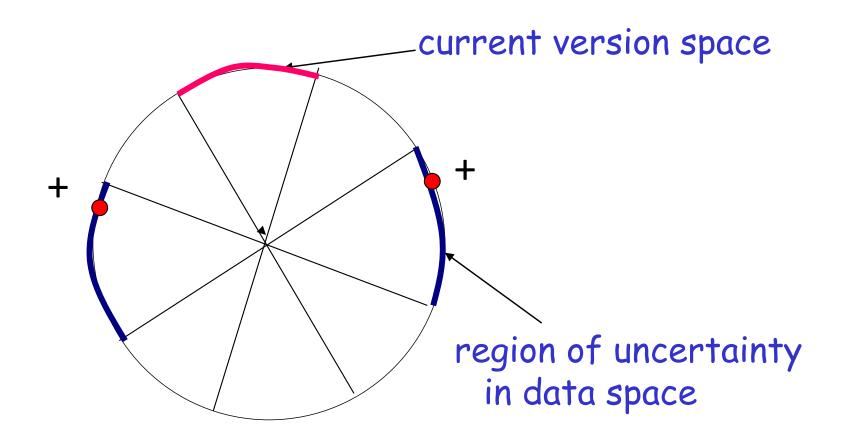

For t = 1,,

Pick a few points at random from the current region of disagreement $DIS(H_t)$ and query their labels.

Let H_{t+1} be the new version space.

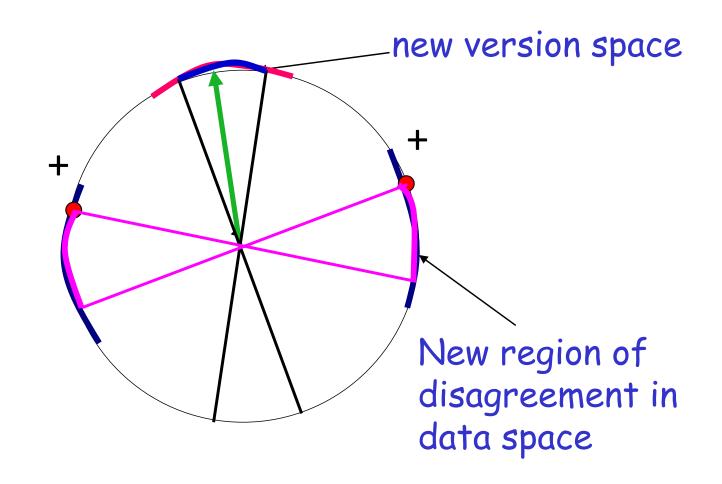

Region of uncertainty [CAL92]

- Current version space: part of C consistent with labels so far.
- "Region of uncertainty" = part of data space about which there is still some uncertainty (i.e. disagreement within version space)

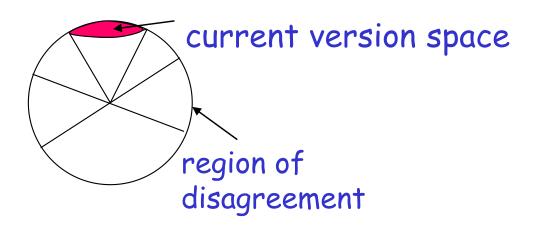

Region of uncertainty [CAL92]

- Current version space: part of C consistent with labels so far.
- "Region of uncertainty" = part of data space about which there is still some uncertainty (i.e. disagreement within version space)

How about the agnostic case where the target might not belong the H?

A² Agnostic Active Learner [BBL'06]

Algorithm:

Let
$$H_1 = H$$
.

For t = 1,,

Careful use of generalization bounds; Avoid the sampling bias!!!!

- Pick a few points at random from the current region of disagreement $DIS(H_t)$ and query their labels.
- Throw out hypothesis if you are statistically confident they are suboptimal.

The DHN Agnostic Active Learner [DHN'07]

```
S=\emptyset (points with inferred labels) T=\emptyset (points with queried labels) For t=1,2,\ldots:
Receive x_t
If (h_{+1}=\mathtt{learn}(S\cup\{(x_t,+1)\},T)) fails: Add (x_t,-1) to S and break If (h_{-1}=\mathtt{learn}(S\cup\{(x_t,-1)\},T)) fails: Add (x_t,+1) to S and break If \mathtt{err}(h_{-1},S\cup T)-\mathtt{err}(h_{+1},S\cup T)>\Delta_t: Add (x_t,+1) to S and break If \mathtt{err}(h_{+1},S\cup T)-\mathtt{err}(h_{-1},S\cup T)>\Delta_t: Add (x_t,+1) to S and break Request y_t and add (x_t,y_t) to T
```

Figure 16: The DHM selective sampling algorithm. Here, $\operatorname{err}(h, A) = (1/|A|) \sum_{(x,y) \in A} 1(h(x) \neq y)$. A possible setting for Δ_t is shown in Equation 1. At any time, the current hypothesis is $\operatorname{learn}(S, T)$.

learn(A, B) returns a hypothesis $h \in \mathcal{H}$ consistent with A, and with minimum error on B. If there is no hypothesis consistent with A, a failure flag is returned.

$$\Delta_t = \beta_t^2 + \beta_t \left(\sqrt{\operatorname{err}(h_{+1}, S \cup T)} + \sqrt{\operatorname{err}(h_{-1}, S \cup T)} \right), \quad \beta_t = C \sqrt{\frac{d \log t + \log(1/\delta)}{t}}$$

When Active Learning Helps. Agnostic case

A² the first algorithm which is robust to noise.

[Balcan, Beygelzimer, Langford, ICML'06] [Balcan, Beygelzimer, Langford, JCSS'08]

"Region of disagreement" style: Pick a few points at random from the current region of disagreement, query their labels, throw out hypothesis if you are statistically confident they are suboptimal.

Guarantees for A² [BBL'06,'08]:

It is safe (never worse than passive learning) & exponential improvements.

· C - thresholds, low noise, exponential improvement,

· C - homogeneous linear separators in Rd,

D - uniform, low noise, only $d^2 \log (1/\epsilon)$ labels.

A lot of subsequent work.

[Hanneke'07, DHM'07, Wang'09, Fridman'09, Kolt10, BHW'08, BHLZ'10, H'10, Ailon'12, ...]

General guarantees for A² Agnostic Active Learner

"Disagreement based": Pick a few points at random from the current region of uncertainty, query their labels, throw out hypothesis if you are statistically confident they are suboptimal. [BBL'06]
How quickly the region of disagreement

collapses as we get closer and closer to optimal classifier

Guarantees for A² [Hanneke'07]:

Disagreement coefficient
$$\theta_{\mathbf{c}^*} = \sup_{\mathbf{r} \geq \eta + \epsilon} \frac{\Pr(DIS(B(c^*, r)))}{r}$$

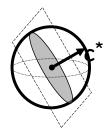

Theorem

$$m = \left(1 + \frac{\eta^2}{\epsilon^2}\right) VCdim(C)\theta_{c^*}^2 \log(\frac{1}{\epsilon})$$

labels are sufficient s.t. with prob. $\geq 1-\delta$ output h with $err(h) \leq \eta + \epsilon$.

Realizable case: $m = VCdim(C)\theta_{c^*}\log(\frac{1}{\epsilon})$

Linear Separators, uniform distr.: $\theta_{c^*} = \sqrt{d}$

Disagreement Based Active Learning

"Disagreement based " algos: query points from current region of disagreement, throw out hypotheses when statistically confident they are suboptimal.

- · Generic (any class), adversarial label noise.
- · Computationally efficient for classes of small VC-dimension

Still, could be suboptimal in label complex & computationally inefficient in general.

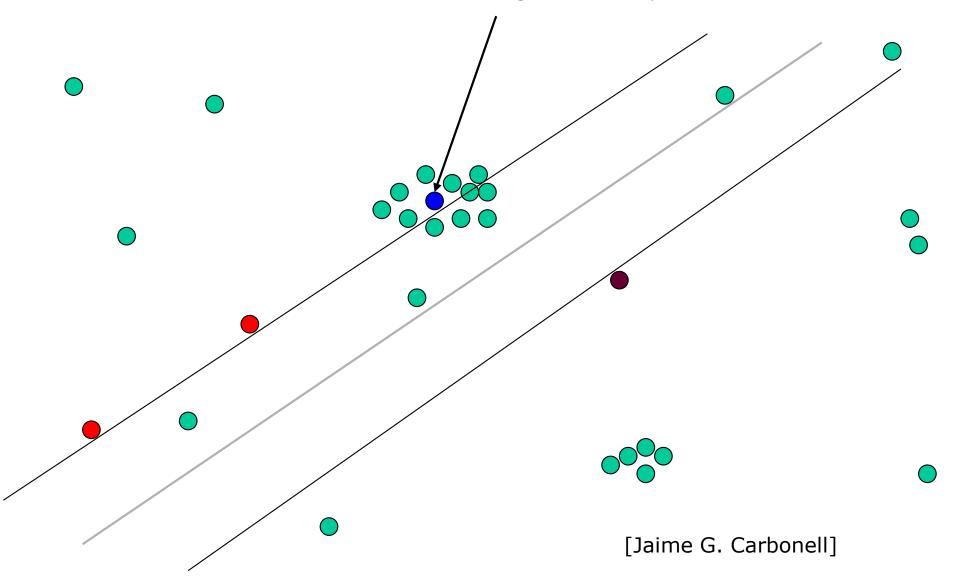

Lots of subsequent work trying to make is more efficient computationally and more aggressive too: [HannekeO7, DasguptaHsuMontleoni'07, Wang'09, Fridman'09, Koltchinskii10, BHW'08, BeygelzimerHsuLangfordZhang'10, Hsu'10, Ailon'12, ...]

Other Interesting ALTechniques used in Practice

Interesting open question to analyze under what conditions they are successful.

Density-Based Sampling

Uncertainty Sampling

Closest to decision boundary (Active SVM) [Jaime G. Carbonell]

Maximal Diversity Sampling

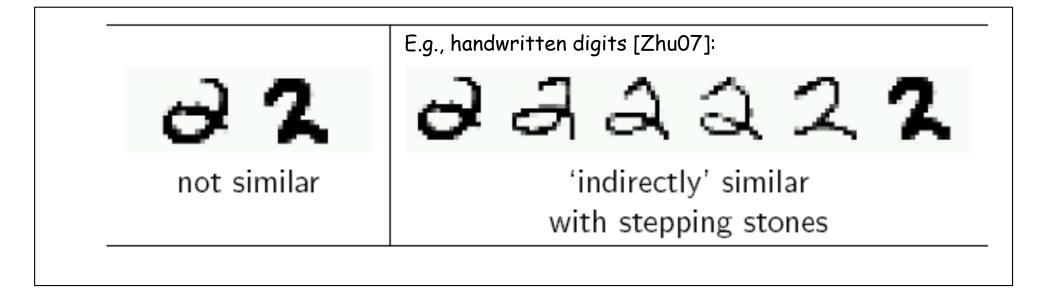

Ensemble-Based Possibilities

Graph-based Active and Semi-Supervised Methods

Graph-based Methods

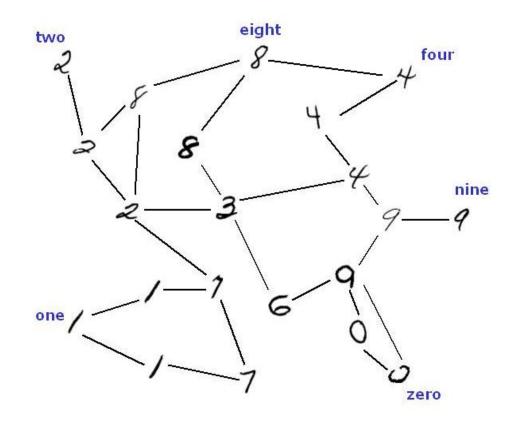

- Assume we are given a pairwise similarity fnc and that very similar examples probably have the same label.
- If we have a lot of labeled data, this suggests a Nearest-Neighbor type of algorithm.
- If you have a lot of unlabeled data, perhaps can use them as "stepping stones".

Graph-based Methods

Idea: construct a graph with edges between very similar examples.

Unlabeled data can help "glue" the objects of the same class together.

Graph-based Methods

Often, transductive approach. (Given L + U, output predictions on U). Are alllowed to output any labeling of $L \cup U$.

Main Idea:

 Construct graph G with edges between very similar examples.

 Might have also glued together in G examples of different classes.

 Run a graph partitioning algorithm to separate the graph into pieces.

Several methods:

- Minimum/Multiway cut [Blum&Chawla01]
- Minimum "Soft-cut" [ZhuGhahramaniLafferty'03]
- Spectral partitioning

- ...

SSL using soft cuts

[ZhuGhahramaniLafferty'03]

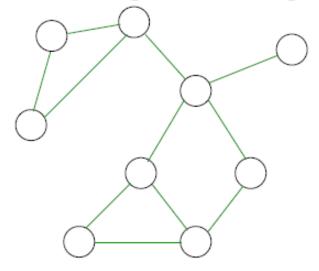

Solve for label function $f(x) \in [0,1]$ to minimize:

$$J(f) = \sum_{edges(i,j)} w_{ij} (f(x_i) - f(x_j))^2 + \sum_{x_i \in L} \lambda (f(x_i) - y_i)^2$$

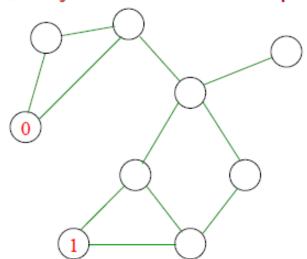

Similar nodes get similar labels (weighted similarity) Agreement with labels (agreement not strictly enforces)

Active learning with label propagation

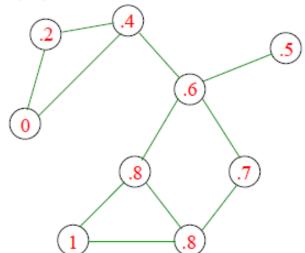

(1) Build neighborhood graph

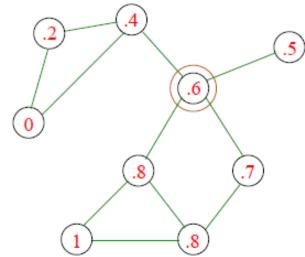

(2) Query some random points

- (3) Propagate labels (using soft-cuts)
- (4) Make query and go to (3)

How to choose which node to query?

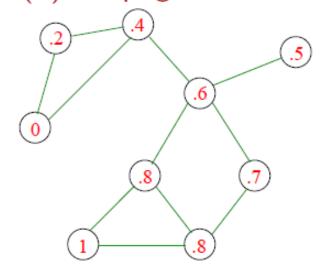

Active learning with label propagation

One natural idea: query the most uncertain point.

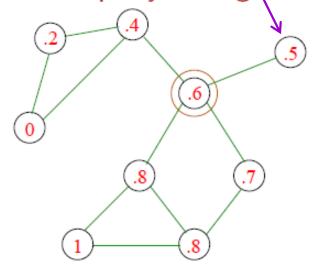

But this has only one edge. Query won't have much impact!

(even worse: a completely isolated node)

(3) Propagate labels (using soft-cuts)

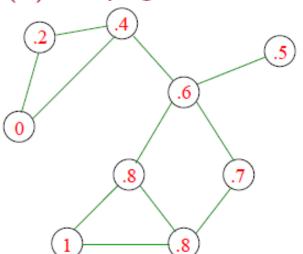

(4) Make query and go to (3)

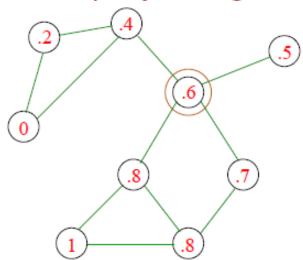

Active learning with label propagation

Instead, use a 1-step-lookahead heuristic:

- For a node with label p, assume that querying will have prob p of returning answer 1, 1-p of returning answer 0.
- Compute "average confidence" after running soft-cut in each case: $p\frac{1}{n}\sum_{x_i}\max(f_1(x_i),1-f_1(x_i))+(1-p)\frac{1}{n}\sum_{x_i}\max(f_0(x_i),1-f_0(x_i))$
- Query node s.t. this quantity is highest (you want to be more confident on average).
 - (3) Propagate labels (using soft-cuts)

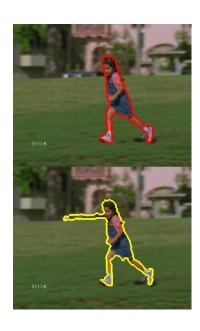

(4) Make query and go to (3)

Active Learning with Label Propagation in Practice

Does well for Video Segmentation (Fathi-Balcan-Ren-Regh, BMVC 11).

What You Should Know

- Active learning could be really helpful, could provide exponential improvements in label complexity (both theoretically and practically)!
- Common heuristics (e.g., those based on uncertainty sampling). Need to be very careful due to sampling bias.
- Safe Disagreement Based Active Learning Schemes.
 - Understand how they operate precisely in noise free scenarios.
